

# San Bernardino basin focal mechanisms reveal signals of interseismic loading and the 1812 Wrightwood earthquake

Michele L. Cooke, Jennifer L. Hatch and Hanna M. Elston

# Normal slip focal mechanisms?

Microseismicity (Yang *et al.* 2012 and subsequent updates) has unexpected normal slip events within the San Bernardino basin between two major strike-slip faults.

Off-Fault Focal Mechanisms Not Representative of Interseismic Fault Loading Suggest Deep Creep on the Northern San Jacinto Fault

M. L. Cooke<sup>1</sup> and J. L. Beyer<sup>1</sup>

<sup>1</sup>Geosciences Department, University of Massachusetts Amherst, Amherst, MA, USA

### Key Points:

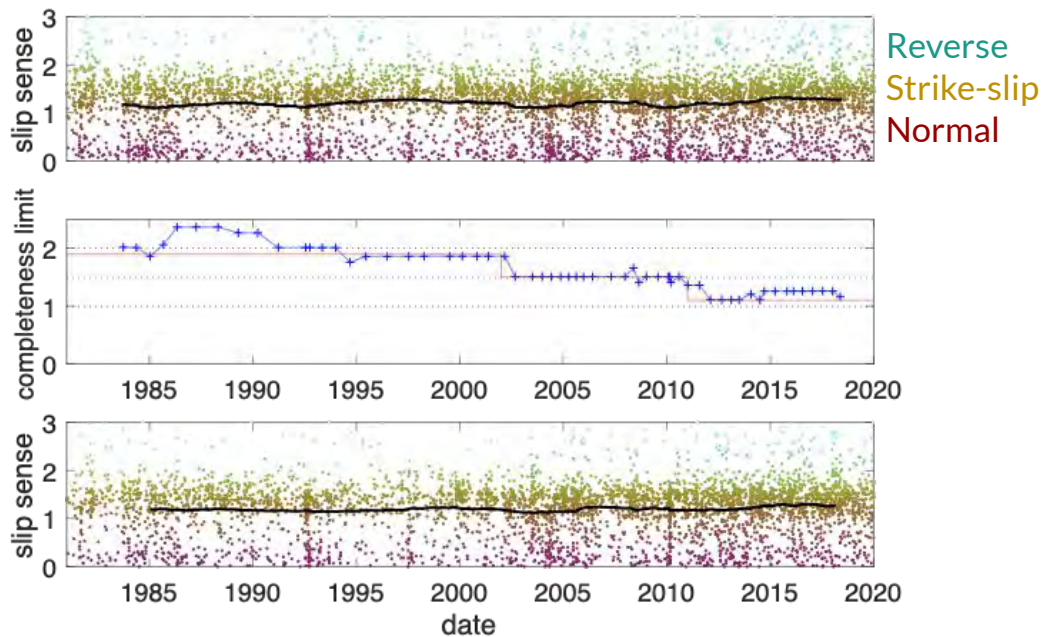

- Crustal deformation models demonstrate the plausibility of deep creep along the northern San Jacinto fault to account for nearby enigmatic normal slip mechanisms

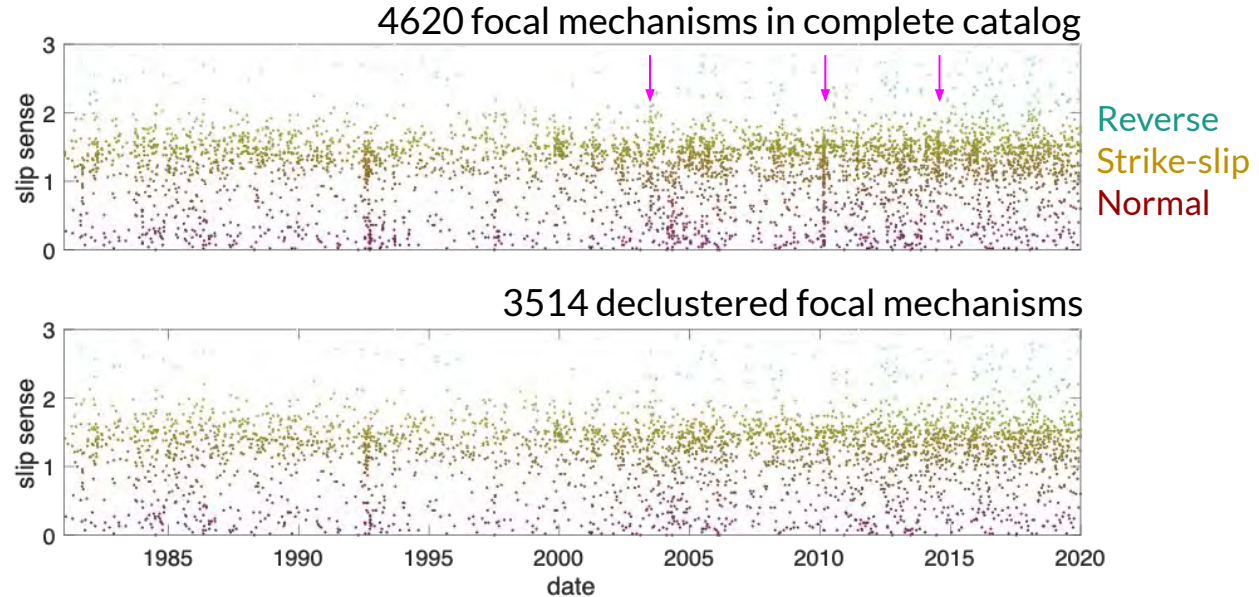

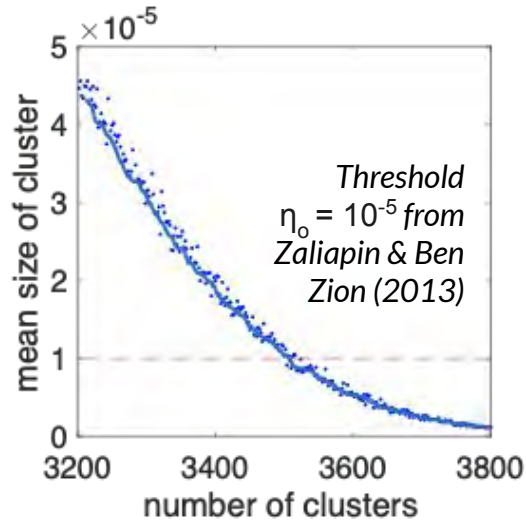

Forward interseismic models with 20 km locking depth predict strike-slip events at the locations of the observed microseismicity.

From Cooke and Beyer (2018)

# Catalog Completeness

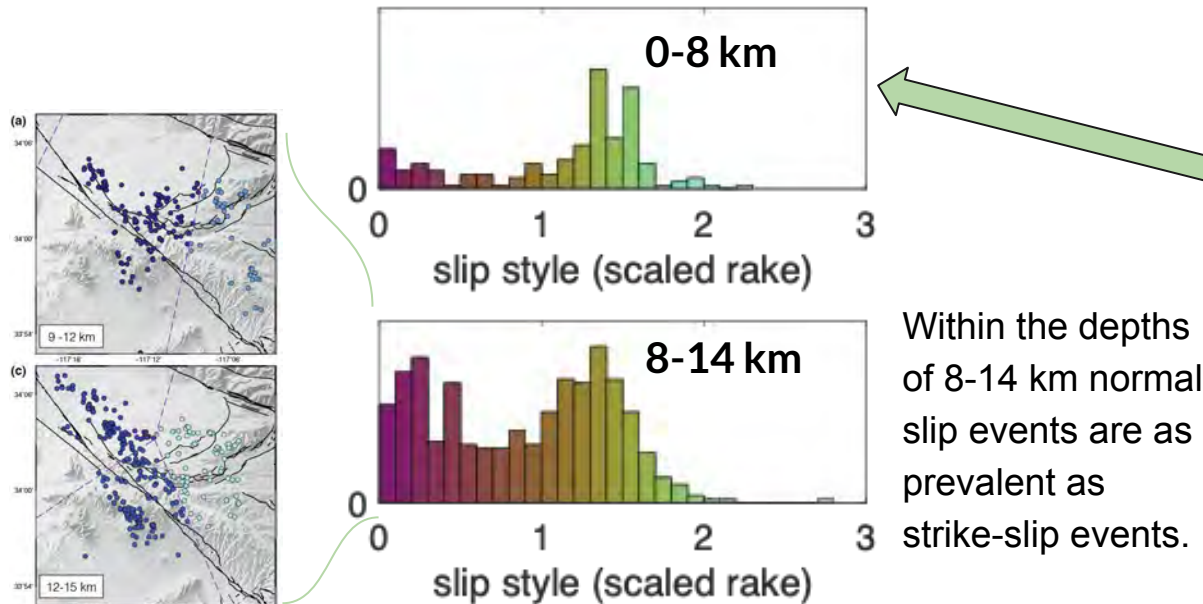

# 3514 declustered events

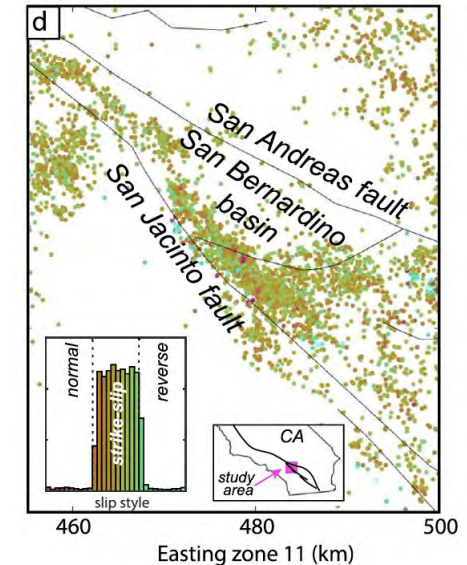

- Spatial and temporal rescaling following *Baiesi & Paczuski* [2004] using parameters from Zaliapin & Ben Zion (2013)
- K-means using squared Euclidean distance to identify clusters
- Choose largest magnitude event in each cluster

# Depth variation within the San Bernardino basin

Interseismic loading produces strike-slip stress state above the locking depth.

# Long-term basin extension

Long term deformation over multiple earthquake cycles shows dilation within the San Bernardino basin.

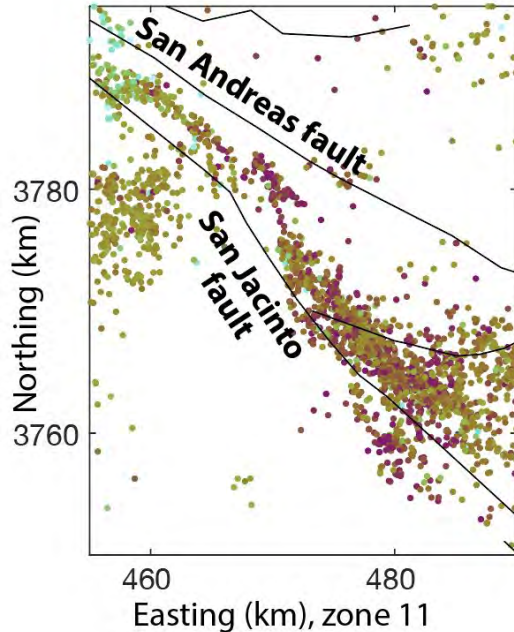

Since normal slip events occur primarily below 8 km depth could the San Jacinto have creep below this depth?

From Cooke and Beyer (2018)

# With SJ locking depth 10km SA 20 km

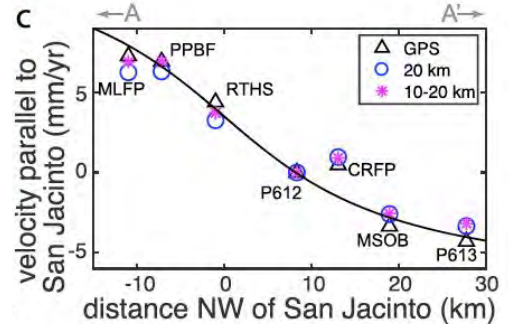

Complete & declustered  
focal mechanisms

Interseismic forward  
model predictions

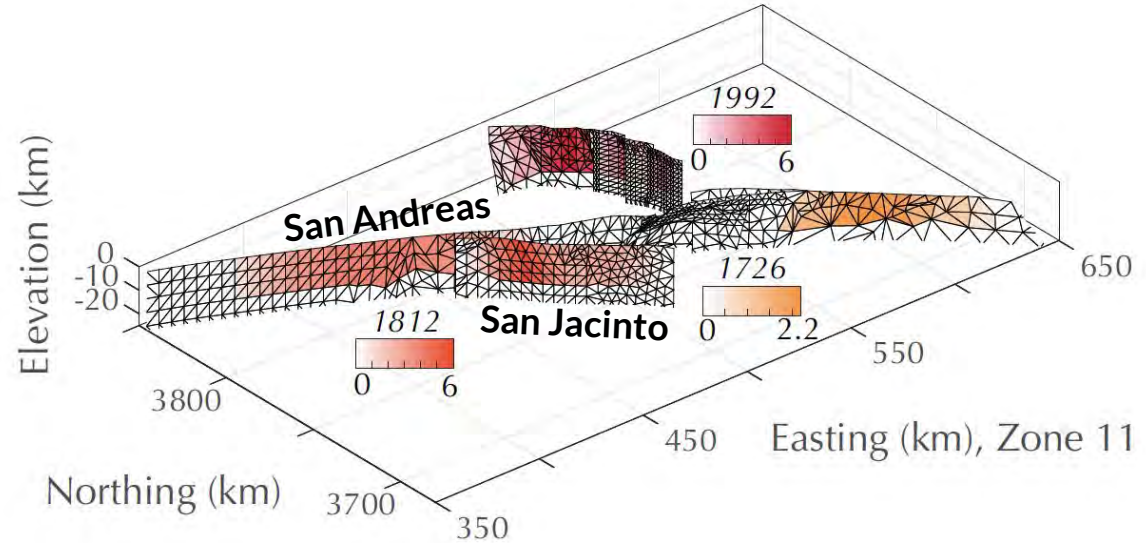

uniform random noise ( $\pm 0.5$ ) added to the  
model predictions to account for heterogeneity

From Cooke and Beyer (2018)

# Wrightwood 1812 earthquake

Rupture extent and slip distribution based on Onderdonk et al., (2013 & 2015) Rockwell et al. (2016) and Lozos (2016)

Hatch et al. (2020) show that recent earthquakes contribute to total stress state on nearby faults

THEMED ISSUE: Seismotectonics of the San Andreas Fault System in the San Geronio Pass Region

## Considering fault interaction in estimates of absolute stress along faults in the San Geronio Pass region, southern California

Jennifer L. Hatch<sup>1</sup>, Michele L. Cooke<sup>1</sup>, Aviel R. Stern<sup>1</sup>, Roby Douilly<sup>2</sup>, and David D. Oglesby<sup>2</sup>

<sup>1</sup>Department of Geosciences, University of Massachusetts, Amherst, Massachusetts 01003, USA

<sup>2</sup>Department of Earth Sciences, University of California, Riverside, California 92521, USA

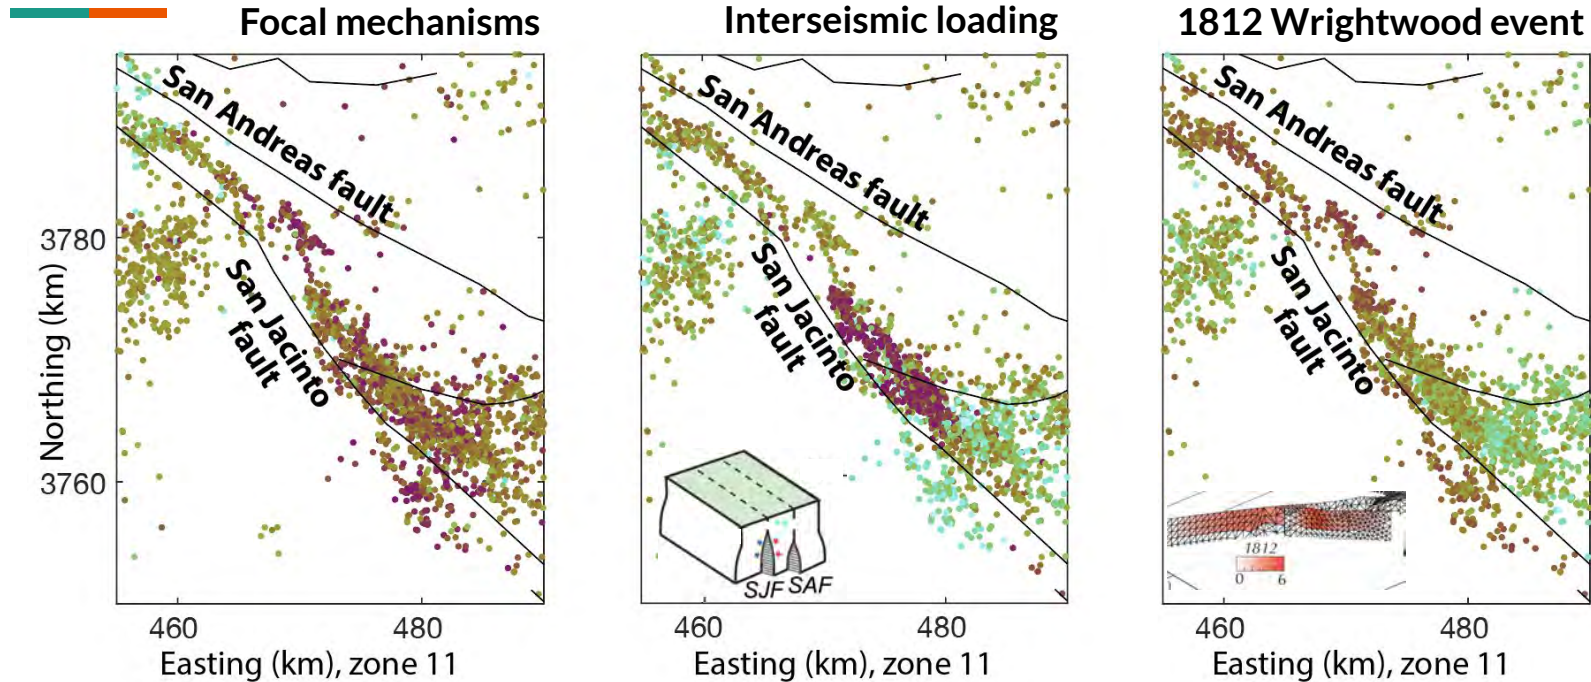

# Two contributions to stress state

Uniform random noise added to model results  $\pm 0.5$

# Recent events & interseismic loading -> stress state

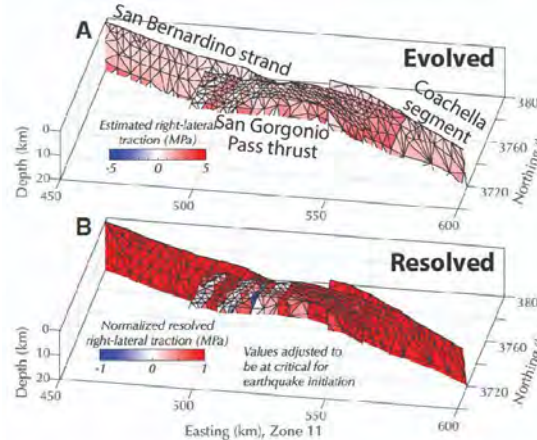

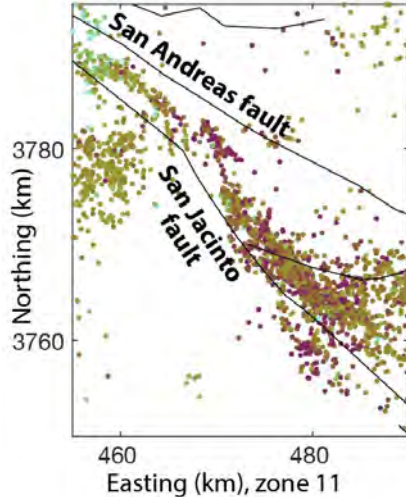

microseismicity may change over EQ cycle  
time

# Regional stress state unreliable where fault behavior and geometry are complex

The regional stress state inaccurately predicts strike-slip microseismicity in the San Bernardino basin.

Stress state depends on interseismic loading & recent earthquakes ← on and off of faults

Focal mechanisms

From Hatch et al. (2020)

Interseismic loading

1812 Wrightwood
